## 124 **1 About this document**

125 This user guideline describes how to define and apply restrictions and extensions to code lists in  
126 UN/EDIFACT messages as well as UN/CEFACT XML messages. In addition, it describes example  
127 processes for validating those messages. The process could be done in one-phase, for which  
128 message structure and value constraints are validated simultaneously (so-called ‘coupled’) or in  
129 two-phases, for which these constraints are validated separately (so-called ‘decoupled’).  
130

131 Parts in this document are excerpts from the XML Naming and Design Rules (UN/CEFACT XML  
132 NDR Rules 2.2), UN/EDIFACT Syntax Implementation Guidelines and OASIS Genericcode/CVA.  
133 They give guidance on how to apply these rules in a real-life environment. The latest version of the  
134 UN/CEFACT XML NDR Rules, version 2.2, allows decoupling of selective or all qualified data  
135 types from a set of value enumerations.

### 136 **1.1 Executive summary**

137 Codes are an essential component of any Machine-To-Machine information flow. Codes have been  
138 developed over time to facilitate the flow of compressed, standardized values that can be easily  
139 validated for correctness to ensure consistent semantics. In a real-life environment, there exist  
140 external circumstances (business needs, laws) that require the extending or restricting (sub-setting)  
141 of standardized code lists in UN/EDIFACT or UN/CEFACT XML messages. Many international,  
142 national and sectoral agencies create and maintain code lists relevant to their area. If required to be  
143 used within an information flow, these code lists will be stored in their own environment and  
144 referred to as external code lists. Although the standardization procedures define how extensions  
145 can be realized by starting a Data Maintenance Request (DMR) there may be time constraints that  
146 solutions need to be found for the time until the final update of the standardized code lists are  
147 published.  
148

149 The UN/CEFACT Code Management project defines the procedures, rules and methodologies for  
150 the following identified issues.

151

#### 152 **1. Version compatibility**

153 The ability to use any version of a code list in association with any version of a message, i.e.  
154 decoupling the versioning of code lists from the business message versions.  
155

156

#### 156 **2. Extending code lists**

157 Evaluate if permanent extensions are possible and desirable.  
158

159

#### 159 **3. Restricting code lists**

160 Provide rules and methodology for restricting code lists for use within specific context. Users of the  
161 UN/CEFACT libraries may identify any sub-set they wish from a specific code list for their own  
162 community requirements.  
163

164

#### 164 **4. Code list validation rules**

165 Provide rules and methodology for how to validate instance documents against an XML Schema or  
166 UN/EDIFACT message type in respect to code lists.  
167

168

#### 168 **5. Temporary codes**

169 Provide rules and methodology for the inclusion of temporary codes that will be replaced by a  
170 permanent code at the next UN/CEFACT standardized release, in essence a temporary extension.  
171

171

172 **6. Externally maintained code lists**

173 Define rules and procedures for referencing code lists maintained by organizations external to  
174 UN/CEFACT, e.g. ISO, ICC, W3C, UNECE.

175  
176 **7. Publication format for code lists**

177 A standard exchange format for code lists.

178 **1.2 Status of this document**

179 This document has been developed in accordance with the UN/CEFACT/TRADE/22 Open  
180 Development Process for Guidelines and approved for publication by the UN/CEFACT Bureau.

181 **1.3 Revision history**

## 212 3 Introduction

213 The main audiences for this document are primarily.

- 214 - Corporate Chief Technology Officers - Government
- 215 - Corporate Chief Technology Officers – Private Sector
- 216 - UN/CEFACT Bureau and Vice Chair persons

### 217 3.1 Structure of this document

- 218 - Chapter: 4 User Requirements
- 219 - Chapter: 5 Using code lists in a real-life environment
- 220 - Chapter: 6 Validating UN/EDIFACT document instances
- 221 - Chapter: 7 Validating UN/CEFACT XML document instances
- 222 - Chapter: 8 Publication Format Code Lists
- 223 - Chapter: 9 Definition of terms

### 224 3.2 Related Documents

- 225 - UN/EDIFACT Directory, Part 4 United Nations Rules for Electronic Data Interchange
- 226 for Administration, Commerce and Transport, Chapter 2.3 - UN/EDIFACT Syntax
- 227 Implementation Guidelines.
- 228 - UN/CEFACT XML Naming and Design Rules for CCTS 2.01 Version 2.2 dated
- 229 MM/DD/2017.
- 230 - ISO 20625 EDIFACT - Rules for generation of XML scheme files (XSD) on the basis
- 231 of EDI(FACT) implementation guidelines
- 232 - Schematron ISO/IEC 19757-3
- 233 - OASIS Context/value association using Genericcode 1.0
- 234 - OASIS Genericcode 1.0

### 235 3.3 Purpose and scope

236 The business goals of this document are:

- 237 - To summarize the steps for creating and/or using extended, restricted, user-defined
- 238 (permanent or temporary) code lists and code lists published by other organizations
- 239 in a real-life environment.
- 240 - To give guidance for validating electronic documents (electronic business messages)
- 241 where the steps above are applied.
- 242

## 243 4 User requirements

244 The essence of all user requirements is flexibility to handle external circumstances (urgent  
245 business needs, laws) that require the extension, restriction of standardized code lists and/or  
246 user-defined code values (permanent or temporary).

247 The requirements gathering phase of the Code Management Project has provided below list:

- 248 - Using own code lists
- 249 - Referring to the code list version actually used
- 250 - Extending code lists (extension)
- 251 - Restricting code lists (restriction)
- 252 - Combining code lists (union)
- 253 - Choosing code lists (choice)
- 254 - Allowing temporary codes
- 255 - Validating code constraints of above requirements
- 256 - Using internationally harmonized code lists (UN/CEFACT and others)
- 257 - Maintaining code lists in an easy manner
- 258 - Obtaining code lists from a standardized publication format

### 259 4.1 The challenge of Interoperability

260 Interoperability is looking at how disparate systems understand each other. In this respect,  
261 it is about receiving code values and behaving as expected. Code values take an important  
262 role in the exchange of transaction data between trading partners. For example, in the case  
263 of a Purchase Order, the receiving system understands the message so that it is now able to  
264 read the Order and start or continue the process at this stage in the Supply Chain.

265 The challenge is that most implementations are separate and different and no one major  
266 player is able to force alignment globally. Typically, misinterpretations occur both before  
267 and after implementations. User-defined code values are often misinterpreted because the  
268 use is not documented properly and therefore systems cannot process these values. The other  
269 challenge is that not everyone needs to implement all standardized code lists and/or code  
270 values specified in the standard as it may not be applicable to them.

### 271 4.2 The challenge of Conformance

272 Conformance is measuring how a document instance makes use of a given standard or  
273 specification. Compliant means that some features in the standard specification are not  
274 implemented, but all features implemented are covered by the specification, and in  
275 accordance with it.

276  
277  
278  
279 **Figure 1: Compliant**

#### 280 4.2.1 Conformance and UN/EDIFACT

281 In the case of UN/EDIFACT messages there is no technical link between the published  
282 message structure and codes used by it. The message structure and codes values used by a  
283 community are specified or referenced within the community Message Implementation  
284 Guide (MIG). In practice user communities often want to be compliant with a published

285 United Nations Standard Message (UNSM) whilst referring to any version of code lists,  
286 restricted, extended or user-defined code lists (permanent or temporary). To be compliant,  
287 the community message standard must be directly derived from an approved UNSM and  
288 having the same function. Therefore, a UN/EDIFACT document instance is commonly only  
289 conformant with a community MIG.

## 290 4.2.2 Conformance and UN/CEFACT XML

291 In the case of UN/CEFACT XML messages there is a technical link between the published  
292 message structure and codes used by it. Using other code values in a XML document  
293 instance than published for the data elements of the message will make the document non-  
294 conformant, unless ‘decoupling’ has been applied to the message standard (as described  
295 within the UN/CEFACT NDR Rules). The term “decoupling” used in this document refers  
296 to decoupling selective or all qualified data types from a set of value enumerations (in other  
297 words separating codes from the message).

## 298 4.2.3 Validation methods

299 This document provides example validation methods to check whether a document instance  
300 conforms or complies to a published UN message standard. The validation of tools is out of  
301 scope of this document and so it is assumed some sort of testing will be carried out, which  
302 can help trading partners to understand and also verify they are conformant or compliant  
303 with the standard or specification.

304 It is, though, important that users will give a true reflection of the actual level of  
305 conformance. Therefore, the conformance statements made by each party should be able to  
306 express this in an unambiguous way.

- 307 - UN/EDIFACT document instance using code values specified or referred within the  
308 MIG is compliant with a published and approved UNSM in case the UN/CEFACT  
309 document instance is generate as a UNSM subset, as described in the UN/EDIFACT  
310 Message Design Guidelines. The document instance it conformant with a published  
311 and approved UNSM in case of pure UNSM, even if non UN code lists or code  
312 values are specified within the MIG.
- 313 - UN/CEFACT XML document instance using the published code values of the  
314 message standard is conformant. It will be non-conformant in case it uses other code  
315 values than published for the message standard, unless ‘decoupling’ of code list  
316 enumerations (code values) has been applied, as described within the UN/CEFACT  
317 XML NDR Rules. Decoupling implies a two-phase validation process as it separates  
318 the checking of message structure constraints and code value constraints..

319

320

321

322

323

324

325

**Note:**

A two-phase validation process consists of checking the well-formedness of an XML instance document and the message structure constraints. These checks are done at the same time (first phase). In addition, the value constraints, including code lists, will be checked within this process (second phase).

## 326 **5 Using code lists in a real-life environment**

### 327 **5.1 Introduction**

328 Codes (or enumerated values) are an integral component of any business-to-business  
329 information flow. Not only should they be understood by humans but also, they should be  
330 fully validated. International standardized codes are harmonized and unambiguous in order  
331 to enforce global trade. International standards organizations, but also many international,  
332 national and sectoral agencies create code lists. The meaning of a code is essential, and its  
333 metadata must be available for the code itself and for the list in which it is adopted. Only  
334 then a code could be fully validated for correctness to ensure consistent data. When used  
335 within an information flow, these code lists will be explicitly referred to.

### 336 **5.2 Extended, restricted, user-defined and other organizations code lists**

337 Users of the UN/CEFACT library may identify any sub-set (restriction) or superset  
338 (extension) they wish from a specific code list for their own user community requirements  
339 by defining code lists. These specific code lists could be based on standardized or user-  
340 defined code lists (permanent or temporary). Each type of code list can easily be  
341 accommodated with the solutions described in the next chapters.

342  
343 **Note:**

344 The term 'code lists', used in this document applies to code lists and identifier lists.  
345  
346  
347  
348

## 349 6 Validating UN/EDIFACT document instances

### 350 6.1 Introduction

351 UNSMs are structured in such a way that they can be used by companies, governmental  
352 agencies and/or other organizations in many different industries. For most industries, a sub-  
353 set of the UNSM has been created because of the restrictive use of the message structure.

354 Users must bear in mind that to comply with the spirit of sub-sets, any sub-set<sup>4</sup> must always  
355 be more restrictive than its parent UNSM. Though validation of restricted, extended, user-  
356 defined and other organizations code lists or code values is done against the ones specified  
357 within the MIG.

358 For UN/EDIFACT message implementations five possible scenarios are clearly defined in  
359 respect to code lists.

### 360 6.2 Restricted code lists

361 In order to identify the restricted UNSM code list(s), the user community concerned should  
362 consider:

- 363 - specifying or referring to the restricted code lists or codes values within the MIG.
- 364 - referring to above in a Trading Partner Agreement.

### 365 6.3 Extended code lists

366 Since the standards maintenance time-scales may delay the implementation of the required  
367 modifications to the UNSM and the code lists repository for some time, users may wish to  
368 implement the needed code list(s) and/or code values immediately so that the message can  
369 be used in their application.

370 In order to identify the extended code lists during the interim period, the user community  
371 concerned should consider:

- 372 - specifying or referring to the extended code lists or code values within the MIG.
- 373 - including an appropriate code in element '0110 Code list directory version number'  
374 of the UNH (only applicable for message syntax version 4). By this, users can refer  
375 to any directory version of a code list, different from the message directory version.
- 376 - including an appropriate code in element '1131 Code Lists Identification Code'  
377 and/or '3055 Code List Responsible Agency' (if available)<sup>7</sup>, in order to identify the  
378 code list properly.
- 379 - referring to above in a Trading Partner Agreement.

380

381

382

383

384

Note on the use of 1131/3055:

This implies such extension is being expressed per individual code list appearing in such message, combined with the more global indication on the message basis. Whenever data element 3055 is used, data element 1131 is mandatory.

---

<sup>4</sup> To provide a unique identification for any particular sub-set of a UNSM, users may wish to assign a code for use in the 'Association assigned code' field of the UNH and/or UNG segments.

<sup>7</sup> See ANNEX A (Informative) Usage of data elements 1131/3055 of the UN/EDIFACT Message Design Guidelines

## 385 6.4 Choosing or combining code lists

386 Users may want to choose another code list for an element than published by UN/CEFACT  
387 or they even want to combine values from different code lists. Most common is choosing  
388 another code list than the published one for the applicable element. The user community  
389 concerned should consider:

- 390 - specifying or referring to the applicable code list or combined code lists within the  
391 MIG. Combined code values from different code lists can be regarded as a user-  
392 defined code list (see next paragraph).
- 393 - including an appropriate code in element '1131 Code Lists Identification Code'  
394 and/or '3055 Code List Responsible Agency' (if available), in order to identify the  
395 code list properly.
- 396 - referring to above in a Trading Partner Agreement.

397

398 Note on the use of 1131/3055:

399 This implies such choice or combination is being expressed per individual code list  
400 appearing in such message, combined with the more global indication on the message  
401 basis. Whenever data element 3055 is used, data element 1131 is mandatory.

402

403 In practice, a combination of code values from different code lists will be stored as a user-  
404 defined code list and referred to within the MIG. As an alternative EDIFACT document  
405 instances and code list could be converted to XML where 'unions' could be created by the  
406 validation process.

## 407 6.5 User-defined code lists (permanent or temporary)

408 User-defined code lists (permanent or temporary) are not uncommon. They often exist in  
409 specific industries. If needed, users could create such code lists and specify the code list for  
410 the applicable element in the MIG. These code lists should be identified as described in  
411 previous paragraph 6.4.

## 412 6.6 Code lists published by other organizations

413 For referencing code lists maintained by organizations external to UN/CEFACT, e.g. ICC,  
414 W3C, CODEX, CITES etcetera the same principle as described for user-defined code lists  
415 could be applied.

## 416 6.7 Validating document instances

417 During the decades of implementing EDIFACT messages many software tools were created  
418 for validating the document instances. Over time systems for processing XML based  
419 documents became more popular, and XML allows easy validation in a self-descriptive  
420 form, a new way for validating EDIFACT files was introduced.

421 For users, the below options are available for validating EDIFACT files:

- 422 - Traditional in-house validation
- 423 - ISO 20625: Converting EDIFACT document instances to XML document instances.  
424 By applying this transformation standard validation tools for XML validation can be  
425 applied.

426 When applying ISO 20625 the principles of validating XML-UN/EDIFACT document  
427 instances in respect to code lists as described in the next chapters do apply. It is therefore  
428 essential that code lists are available in an XML format.  
429

DRAFT

## 430 7 Validating UN/CEFACT XML document instances

### 431 7.1 Introduction

432 UN/CEFACT XML messages are structured in such a way that they can be used by  
 433 companies, governmental agencies and/or other organizations in many different industries.  
 434 The user requirements regarding code management (see chapter 4), can all be fulfilled when  
 435 for these UN/CEFACT XML messages ‘decoupling’ has been applied. The present  
 436 published versions of UN/CEFACT XML message standards validates the messages  
 437 structure and code values of a document instance simultaneously. Decoupling separates code  
 438 value validation from message structure validation.

439 The latest UN/CEFACT XML NDR version allows flexible use of code values, code lists  
 440 and identifier lists by allowing ‘decoupling’ of code values.

441 This chapter highlights the example methodologies that should be applied for restricted,  
 442 extended, user-defined (permanent or temporary) code lists and other organizations code  
 443 lists or code values.

444 Users of a ‘coupled’ version of the message standard may even want to restrict or extend  
 445 code values to the code lists schemas or even introduce other code list schemas. By changing  
 446 the published message standard, the validation process will be non-conformant with the  
 447 published message standard. In order to be conformant with the published message standard,  
 448 these users should implement a ‘decoupled’ version of the message standard. The validation  
 449 process becomes then a two-phase process.

450 In the below simplified fragment of the qualified data type schema (left column), the  
 451 qualified data type ‘DocumentCodeType’ is ‘coupled’ by means of the specified code list  
 452 module (clm61001) which is being imported. The namespace, import declaration and  
 453 extension base are marked grey.

454 In the right column, the qualified data type ‘DocumentCodeType’ is ‘decoupled’ by removal  
 455 of the code list module import and namespace declaration. The extension base  
 456 ‘DocumentCodeContentType’ is no longer linked to the code list module. Therefore, a  
 457 simple type ‘DocumentCodeContentType’ has been specified. In addition, the simple type  
 458 for the list agency ID ‘DocumentCodeListAgencyIDContentType’ does not have any  
 459 enumeration values.

460

Qualified Data Type Schema: coupled version	Qualified Data Type Schema: decoupled version
<pre> &lt;xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema" xmlns:qdt="urn:un:unece:unefact:data:Standard:QualifiedData Type:21" xmlns:ccts="urn:un:unece:unefact:documentation:standard:Core ComponentsTechnicalSpecification:2" xmlns:udt="urn:un:unece:unefact:data:standard:UnqualifiedData Type:21" xmlns:clm61001="urn:un:unece:unefact:codelist:standard:UNEC E:DocumentNameCode:D16B" &gt; &lt;xsd:import namespace="urn:un:unece:unefact:data:standard:UnqualifiedData Type:21" schemaLocation="UnqualifiedDataType_21p0.xsd"/&gt; &lt;xsd:import namespace="urn:un:unece:unefact:codelist:standard:UNECE:Doc umentNameCode_Invoice:D16B" schemaLocation="../../codelist/standard/UNECE_DocumentName Code_Invoice_D16B.xsd"/&gt; &lt;xsd:simpleType name=DocumentCodeListAgencyIDContentType"&gt; </pre>	<pre> &lt;xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema" xmlns:qdt="urn:un:unece:unefact:data:Standard:QualifiedData Type:21" xmlns:ccts="urn:un:unece:unefact:documentation:standard:Cor eComponentsTechnicalSpecification:2" xmlns:udt="urn:un:unece:unefact:data:standard:UnqualifiedDat aType:21" targetNamespace="urn:un:unece:unefact:data:Standard:Qualifie dDataType:21" elementFormDefault="qualified" version="21.0"&gt; &lt;xsd:import namespace="urn:un:unece:unefact:data:standard:UnqualifiedDa taType:21" schemaLocation="UnqualifiedDataType_21p0.xsd"/&gt; &lt;xsd:simpleType name=DocumentCodeContentType"&gt;   &lt;xsd:restriction base="xsd:token"/&gt; &lt;/xsd:simpleType&gt; </pre>

<pre> &lt;xsd:restriction base="xsd:token"&gt;   &lt;xsd:enumeration value="6"&gt; &lt;/xsd:restriction&gt; &lt;/xsd:simpleType&gt; &lt;xsd:complexType name="DocumentCodeType"&gt;   &lt;xsd:simpleContent&gt; &lt;xsd:extension base="clm61001:DocumentNameCodeContentType"&gt;   &lt;xsd:attribute name="listID" type="xsd:token" use="optional" fixed="1001"/&gt;   &lt;xsd:attribute name="listAgencyID" type="qdt:DocumentCodeListAgencyIDContentType" use="optional" fixed="6"/&gt;   &lt;xsd:attribute name="listVersionID" type="xsd:token" use="optional" fixed="D16B"/&gt;   &lt;xsd:attribute name="name" type="xsd:string" use="optional"/&gt;   &lt;xsd:attribute name="listURI" type="xsd:anyURI" use="optional"/&gt; &lt;/xsd:extension&gt; &lt;/xsd:simpleContent&gt; &lt;/xsd:complexType&gt; </pre>	<pre> &lt;xsd:simpleType name= DocumentCodeListAgencyIDContentType"&gt;   &lt;xsd:restriction base="xsd:token"/&gt; &lt;/xsd:simpleType&gt; &lt;xsd:complexType name="DocumentCodeType"&gt;   &lt;xsd:simpleContent&gt;   &lt;xsd:extension base="qdt:DocumentCodeContentType"&gt;     &lt;xsd:attribute name="listID" type="xsd:token" default="1001"/&gt;     &lt;xsd:attribute name="listAgencyID" type="qdt:DocumentCodeListAgencyIDContentType" default="6"/&gt;     &lt;xsd:attribute name="listVersionID" type="xsd:token" use="optional" default="D16B"/&gt;     &lt;xsd:attribute name="name" type="xsd:string"/&gt;     &lt;xsd:attribute name="listURI" type="xsd:anyURI"/&gt;   &lt;/xsd:extension&gt;   &lt;/xsd:simpleContent&gt; &lt;/xsd:complexType&gt; </pre>
--	---

Figure 2: Coupled and decoupled code lists

462

463

464

465

466

In the case of coupled code list modules, the supplementary components of the qualified data type have ‘fixed’ values (marked blue). Using other values in the XML document instance will invoke a validation error during validation.

467

468

469

470

In the case of decoupled code list modules, the supplementary components of the qualified data type have ‘default’ values (marked yellow), which have to be changed by the user when other codes values are used than those in the referenced code list. This is necessary to avoid misinterpretations.

471

472

473

In the below example, the latest version ID of the code list ‘D17B’ is specified instead of the default ‘D16B’ version. In addition, the code value ‘889’ from code list ‘D17B’ is used for the element ‘TypeCode’.

474

<i>Qualified data type coupled</i>	<i>Qualified data type decoupled</i>
<i>Supplementary components:</i> - listID “fixed” = 1001, - listAgencyID “Fixed” = 6, - listVersionID “Fixed” = D16B	<i>Supplementary components:</i> - listID “Default” = 1001, - listAgencyID “Default” = 6 - listVersionID “Default” = D16B
<i>XML document instance fragment</i>	<i>XML document instance fragment</i>
<ram:TypeCode listID="1001" listAgencyID="6" listVersionID="D16B">385</ram:TypeCode>	<ram:TypeCode listID="1001" listAgencyID="6" listVersionID="D17B">889</ram:TypeCode>

Figure 3: Supplementary Components (coupled and decoupled)

476

479

480

481

The use of default values in the supplementary components of the qualified data reminds the user of UN/CEFACT available code lists and recommendations.

482

483

484

485

In below examples, a combination and alternative usage of code lists is specified by XML declarations in the qualified data type. The code list metadata, such as agency ID, is not specified because multiple code lists are declared for a single qualified data type. By this, the metadata of the code lists becomes unambiguous and cannot be validated.

486

487

A two-phase validation process, which uses ‘decoupling’ and a rule-based validation language, such as Schematron, solves the problem for these scenarios.

Union: XML declarations qualified data type	Choice: XML declarations qualified data type
<pre> &lt;xsd:simpleType name="AccountDutyTypeCode"&gt; &lt;xsd:annotation&gt; ...see annotation... &lt;/xsd:annotation&gt; &lt;xsd:union memberType= "clm64437:AccountingTypeCodeContentType" "clm65153:DutyTaxFeeTyoeCodeContentType" &lt;/xsd:simpleType&gt; </pre>	<pre> &lt;xsd:complexType name="PersonPropertyCodeType"&gt; &lt;xsd:annotation&gt; ... see annotation ... &lt;/xsd:annotation&gt; &lt;xsd:choice&gt; &lt;xsd:element ref="clm63479:MaritalCode"/&gt; &lt;xsd:element ref="clm63499:GenderCode"/&gt; &lt;/xsd:choice&gt; &lt;/xsd:complexType&gt; </pre>

488 **Figure 4: Union and choice (coupled code list modules)**

## 489 7.2 One-phase validation process

490 In order to fulfil all user requirements, as decribed in chapter 4, existing published  
491 standardized code lists have to be changed and “saved as” when choosing for a one-phase  
492 validation process method<sup>10</sup>.

493 Changing existing message standards is for most users not preferable, because the XML  
494 document instance will be non-conformant with the published message standard. For those  
495 users, the two-phase validation process methods<sup>11</sup> are available.

496 For UN/CEFACT XML message implementations five possible scenarios are clearly  
497 defined in respect to code lists.

### 498 7.2.1 Restricted code lists

499 In case of allowing users to change existing code list schemas, they could create additional  
500 schemas per code list defining those restricted code lists, as described in the NDR  
501 specification. The software performing the validation compares the XML message  
502 document instance against the restricted code list module schema.

503 To ensure interoperability the usage of restricted code lists must be agreed on in a Trading  
504 Partner Agreement and/or a MIG.

505 The following steps have to be performed for restriction of a published UN/CEFACT code  
506 list:

- 507 1. Create a new code list schema file for the restricted code list.
- 508 2. Modify the original qualified data type schema so that the corresponding type refers  
509 to the newly created code list schema.

### 510 7.2.2 Extended code lists

511 The same procedure as described in previous paragraph can be applied for extending existing  
512 code list module schemas. The software performing the validation compares the XML  
513 message document instance against the modified code list module schema and qualified data  
514 type schema.

### 515 7.2.3 Choosing or combining code lists

516 The UN/CEFACT NDR specification also describes choosing or combining values from  
517 different code lists by using either the xsd:choice or xsd:union elements. There are examples

<sup>10</sup> Both message structure and code values constraints are validated simultaneously.

<sup>11</sup> Message structure and code values constraints are validated separately.

518 provided in this document for these options (see §7.2). For further details we refer to the  
 519 UN/CEFACT NDR specification. As mentioned in paragraph 7.2, the xsd:choice and  
 520 xsd:union implementation within the qualified data type, do not address supplementary  
 521 component differences, as they can only be declared for a single qualified data type.

## 522 7.2.4 User-defined code lists (permanent or temporary)

523 User-defined code lists, either permanent or temporary, are not uncommon. They often exist  
 524 in specific industries. If needed, users could create such code lists modules for the applicable  
 525 qualified data types specified within the qualified data type schema. A user-defined code list  
 526 can often be regarded as an extended code list (see example §7.2.7). The user creates a new  
 527 code list schema module and modifies the original qualified data type schema so that the  
 528 corresponding type refers to the user-defined code list schema.

## 529 7.2.5 Code lists published by other organizations

530 For referencing code lists maintained by organizations external to UN/CEFACT, e.g. ICC,  
 531 W3C, CODEX, CITES etcetera the same principle as described in the preceding paragraph  
 532 would be applied. The user modifies the original qualified data type schema so that the  
 533 corresponding type refers to the user-defined code list schema.

## 534 7.2.6 Example for a restricted code list

535 To demonstrate the methodology the use case of restricting the valid currencies in an XML  
 536 document instance could be looked at. In this example only the use of the Euro currency  
 537 should be valid in the corresponding user community. The corresponding schema then could  
 538 look like shown in Figure 5. In this example, the code list schema is saved as **Invoice\_**  
 539 **ISO\_ISO3AlphaCurrencyCode\_2012-08-31.xsd**.

540 The schema for the qualified data types now needs to be adjusted to the new code list file.  
 541 Only the relevant parts are shown in the following figure. It is allowed to alter the namespace  
 542 prefix accordingly. For simplification, the original namespace prefix is kept.  
 543

Qualified data type schema	Code list schema
<pre>&lt;xs:schema ... xmlns:clm5ISO42173A= "urn:un:unece:unefact:codelist:standard: ISO:ISO3AlphaCurrencyCode:INVOICE" ... elementFormDefault="qualified" version="1.0"&gt; &lt;xs:import namespace="urn:un:unece:unefact:codelist:standard: ISO:ISO3AlphaCurrencyCode:INVOICE" schemaLocation="Invoice_ ISO_ISO3AlphaCurrencyCode_2012-08-31.xsd"/&gt; ... &lt;/xs:schema&gt;</pre>	<pre>&lt;xs:schema xmlns:clm5ISO42173A:INVOICE= "urn:un:unece:unefact:codelist:standard: ISO:ISO3AlphaCurrencyCode:INVOICE" xmlns:xs="http://www.w3.org/2001 /XMLSchema" targetNamespace= "urn:un:unece:unefact:codelist:standard:ISO: ISO3AlphaCurrencyCode:INVOICE" elementFormDefault="qualified" version="9.5"&gt; &lt;xs:simpleType name="ISO3AlphaCurrencyCodeContentType"&gt; &lt;xs:restriction base="xs:token"&gt; &lt;xs:enumeration value="EUR"/&gt; &lt;xs:enumeration value="USD"/&gt; &lt;/xs:restriction&gt; &lt;/xs:simpleType&gt; &lt;/xs:schema&gt;</pre>

545 **Figure 5: Restricted code list (code list schema and qualified data type)**  
 546

## 548 7.2.7 Example for an extended code list

549 To demonstrate the methodology the use case of extending the valid VAT category codes in  
 550 an XML document instance should be looked at. In this example, the existing code list  
 551 should be valid and a new code value 'BB' should be added. The corresponding code list  
 552 schema then could look like shown in Figure 6. In this example, the code list schema is saved  
 553 as VATExtended\_UNECE\_DutyorTaxorFeeCategoryCode\_D17B.xsd.

554 The schema for the qualified data types now needs to be adjusted to the new code list file.  
 555 Only the relevant parts are shown in the following figure. It is allowed to alter the namespace  
 556 prefix accordingly. For simplification, the original namespace prefix is kept.

557

Qualified data type schema	Code list schema
<pre> &lt;xs:schema ... xmlns: clm65305="urn:un:unece:uncefact:codelist :standard:UNECE: DutyorTaxorFeeCategoryCode :D17B:VATEXTENDED ... elementFormDefault="qualified" version="1.0"&gt; &lt;xs:import namespace=" urn:un:unece:uncefact:codelist:standard:UNECE :DutyorTaxorFeeCategoryCode:D17B :VATEXTENDED " schemaLocation=" VATExtended_UNECE_DutyorTaxorFee CategoryCode_D17B.xsd"/&gt; ... &lt;/xs:schema&gt; </pre>	<pre> &lt;xs:schema xmlns:clm65305= "urn:un:unece:uncefact:codelist: standard:UNECE:DutyorTaxorFeeCategoryCode :D17B:VATEXTENDED" xmlns:xs="http://www.w3.org/2001/XMLSchema" targetNamespace="urn:un:unece:uncefact :codelist:standard:UNECE :DutyorTaxorFeeCategoryCode:D17B :VATEXTENDED" elementFormDefault="qualified" version="1.5"&gt;   &lt;xs:simpleType name="DutyorTaxorFeeCategoryCodeContentType"&gt;   &lt;xs:restriction base="xs:token"&gt;     &lt;xs:enumeration value="A"/&gt;     &lt;xs:enumeration value="AA"/&gt;     &lt;xs:enumeration value="AB"/&gt;     &lt;xs:enumeration value="AC"/&gt;     &lt;xs:enumeration value="AD"/&gt;     &lt;xs:enumeration value="AE"/&gt;     &lt;xs:enumeration value="B"/&gt;     &lt;xs:enumeration value="BB"/&gt;     &lt;xs:enumeration value="C"/&gt;     &lt;xs:enumeration value="D"/&gt;     &lt;xs:enumeration value="E"/&gt;     &lt;xs:enumeration value="F"/&gt;     &lt;xs:enumeration value="G"/&gt;     &lt;xs:enumeration value="H"/&gt;     &lt;xs:enumeration value="I"/&gt;     &lt;xs:enumeration value="J"/&gt;     &lt;xs:enumeration value="O"/&gt;     &lt;xs:enumeration value="S"/&gt;     &lt;xs:enumeration value="Z"/&gt;   &lt;/xs:restriction&gt; &lt;/xs:simpleType&gt; &lt;/xs:schema&gt; </pre>

560

Figure 6: Extended code list (code list schema and qualified data type)

## 562 7.2.8 Impacts for a real-life environment

563 The advantage is that still a one-phase validation can be performed. But the modified code  
 564 list schema needs to be published and maintained within the user community in order to  
 565 simplify implementation and keep consistency. All users need to agree on using the modified  
 566 code list schema and to be non-conformant to the published message standard.

567 The non-conformance issue can be avoided by applying a two-phase validation process (see  
568 next paragraph) in which code list are decoupled from the message standard.

### 569 7.3 Two-phase validation process

570 In a two-phase validation process method<sup>12</sup> structural validation is executed independent of  
571 value validation, and done in the first phase of the process. The validation of code values is  
572 performed in a second phase following a successful first phase validation. This two-phase  
573 validation process method is ideal for users who prefer maximum flexibility regarding code  
574 lists and/or code values.

575 The two-phase validation methods, described in this document, are rule based. Schematron  
576 is used as the rule based validation language. Schematron is capable of expressing  
577 constraints in ways that other XML schema languages like XML Schema and DTD cannot.  
578 For example, it can require that the content of an element be controlled by one of its siblings.  
579 Or it can request or require that an element must have specific attributes (e.g. code list  
580 metadata and/or specific code values).

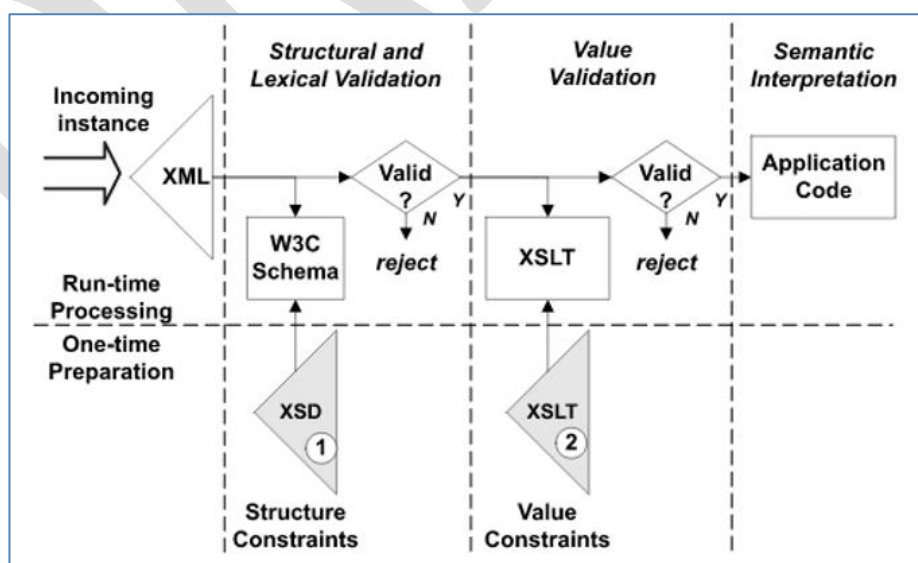

581 Figure 7 illustrates the essence of the two-phase validation process. It shows the distinction  
582 between structural constraints validation (phase 1) and value validation (phase 2). Structural  
583 validation is typically performed by using XSD schema (marked '1') and value constraint  
584 validation is typically performed by using XSLT (marked '2'). As constraints are specified  
585 as rules using Schematron, they will be deployed as XSLT code, making it practical for  
586 applications.

587 Trading partners can execute value validation using whatever tools are appropriate to their  
588 environment.

589 In addition to the validation performed by the inhouse application, trading partners may use  
590 one of the following commonly used standards for value constraints validation.

- 591 1. Schematron/XSLT (ISO/IEC 19757-3 / W3C)
- 592 2. Schematron/XSLT using Genericcode/CVA (OASIS)

593

594  
595

Figure 7: Two-phase validation process

<sup>12</sup> Message structure and code values constraints are validated separately.

### 596 7.3.1 ISO Schematron/XSLT

597 Schematron is a rule-based validation language that uses context expressions. A Schematron  
 598 schema makes assertions applied to a specific context within the XML document. If an  
 599 assertion fails a diagnostic message can be displayed. In order to implement the context  
 600 expressions used in the Schematron rules, XPath is used with various extensions provided  
 601 by XSLT. As path expressions are built on top of XPath and XSLT, one should implement  
 602 Schematron using XSLT (an assert element has a test attribute, which is an XSLT pattern).  
 603 XML documents have data elements to be validated. The context location of those data  
 604 elements is represented using XPath.

605 For UN/CEFACT XML message implementations five possible scenarios are clearly  
 606 defined in respect to code lists. In below paragraphs, these are specified for both two-phase  
 607 validation process methods.

#### 608 7.3.1.1 Restricted code lists

609 The restricted (code) values for a specific context within the XML document, such as  
 610 ExchangedDocument/TypeCode, can be expressed as an assertion in a Schematron rule. In  
 611 addition, assertions for the supplementary components can be included. From the  
 612 Schematron file an XSLT file can be generated automatically using a tool.

613 In below example, the allowed code values and supplementary codes have been specified as  
 614 a Schematron rule.

615 This simplified example allows only the exchanged document type codes (in an invoice):

- 616 - code values '380' and '385'
- 617 - *code list ID '1001'*
- 618 - *list agency ID '6'*
- 619 - *code list version 'D16B'*.
- 620 - *code value length is restricted to 3 characters and must be numeric.*
- 621

Schematron rule
<pre> &lt;rule context="/rsm:CrossIndustryInvoice/rsm:ExchangedDocument/ram:TypeCode"&gt;   &lt;assert test="@listID = '1001'" &gt; Value must be 1001, found &lt;value-of select="."/ &gt; &lt;/assert&gt;   &lt;assert test="@listAgencyID = '6'"&gt; Value must be 6, found &lt;value-of select="."/ &gt; &lt;/assert&gt;   &lt;assert test="@listVersionID = 'D16B'"&gt; Value must be D16B, found &lt;value-of select="."/ &gt; &lt;/assert&gt;   &lt;assert test="=380 or =385"&gt; Value must be 380 or 385, found &lt;value-of select="."/ &gt; &lt;/assert&gt;   &lt;assert test="string-length(.) = 3"&gt;Length of code '&lt;value-of select="."/ &gt;' is longer than 3 characters.&lt;/assert&gt;   &lt;assert test="number(.)"&gt;The code is not a number.&lt;/assert&gt; &lt;/rule&gt; </pre>

622 **Figure 8: Schematron rule (restricted code list)**

623 A user most likely wants to link code values from his 'restricted' UN/CEFACT code list  
 624 schema module instead of specifying each allowed code value within an assertion manually.  
 625 An important feature to note is that, because of XSLT's *Document()* function, a Schematron  
 626 assertion test can refer to data in a different document from the context document. This  
 627 allows Schematron to be used to validate against a code list located externally to the schema  
 628 (this can be in any XML document type). Although the function *Document()* includes  
 629 external codes values for this purpose, it would still be quite some time consumed to write  
 630 the needed code.

#### 631 7.3.1.2 Extended code lists

632 The extended code values for a specific context within the XML document instance, such as  
 633 ExchangedDocument/TypeCode, can be expressed as assertions in a Schematron rule. The

634 extended code values could be added to an existing assertion or by adding an assertion next  
 635 to the one holding the base set of code values. In addition, assertions for the supplementary  
 636 components can be included as well. From the Schematron file an XSLT file can be  
 637 generated automatically by using a tool.

638 In below example, the allowed code values and supplementary codes have been specified as  
 639 a Schematron rule.

640 This simplified example allows only the exchanged document type codes (in an invoice):

- 641 - code values '380', '385' and '889' (added),
- 642 - *code list ID '1001'*
- 643 - *list agency ID '6'*
- 644 - *code list version 'D16B'*.
- 645 - *The length of the code value is restricted to 3 characters and must be numeric.*
- 646

Schematron rule
<pre> &lt;rule context="/rsm:CrossIndustryInvoice/rsm:ExchangedDocument/ram:TypeCode"&gt;   &lt;assert test="@listID = '1001'" &gt; Value must be 1001, found &lt;value-of select="."/&gt; &lt;/assert&gt;   &lt;assert test="@listAgencyID = '6'"&gt; Value must be 6, found &lt;value-of select="."/&gt; &lt;/assert&gt;   &lt;assert test="@listVersionID = 'D16B'"&gt; Value must be D16B, found &lt;value-of select="."/&gt; &lt;/assert&gt;   &lt;assert test=".=380 or .=385 or .=889"&gt; Value must be 380 or 385 or 889, found &lt;value-of select="."/&gt; &lt;/assert&gt;   &lt;assert test="string-length(.) = 3"&gt;Length of code '&lt;value-of select="."/&gt;' is longer than 3 characters.&lt;/assert&gt;   &lt;assert test="number(.)"&gt;The code is not a number.&lt;/assert&gt; &lt;/rule&gt; </pre>

647 **Figure 9: Schematron rule (extended code list)**

648 A user most likely wants to link code values from his 'extended' UN/CEFACT code list  
 649 schema module instead of specifying each allowed code value within an assertion manually.  
 650 The function *Document()* could be used to link external located code values for this purpose.

### 651 7.3.1.3 Choosing or combining code lists

652 Combined code lists can be achieved by adding multiple assertions using function  
 653 *Document()* in order to refer to multiple code lists or by specifying the combined code  
 654 values as one or multiple assertion. Alternative code lists to choose from, can be specified  
 655 as different Schematron rules referring to externally located code lists using the Schematron  
 656 function *Document()* or by specifying the code values as an assertion.

### 657 7.3.1.4 User-defined code lists (permanent or temporary)

658 User-defined code lists, either permanent or temporary, are not uncommon. They often exist  
 659 in specific industries. These code lists could be regarded as additional or extended code lists.  
 660 For both assertions within Schematron rules can be used to specify the code values or refer  
 661 to externally located code lists using the Schematron function *Document()*.

### 662 7.3.1.5 Code lists published by other organizations

663 An external maintained code list could be treated as a user defined code list using assertions  
 664 to specify the needed code values or refer to externally located code lists using the  
 665 Schematron function *Document()*.

### 666 7.3.1.6 Impacts for a real-life environment

667 From a user-perspective, the Schematron/XSLT validation method requires users to take the  
 668 following steps:

- 669
- 670
- 671
- 672
- 673
- 674
- 675
- Create code lists (including metadata) in such a way that Schematron rules can validate these data.
  - Write Schematron rules for checking the allowed code value(s), supplementary components, appropriate document context(s), all including error messages.
  - Use a tool which generates the XSLT file from the Schematron file.
  - Create an environment managing the Schematron rules in order to easy maintenance on code lists and code values.

### 676 7.3.2 ISO Schematron/XSLT – using Genericode/CVA

677 This method uses, in addition to ISO Schematron/XSLT, a standard representation format  
678 of code lists named ‘genericode’ and associations that link context and values named  
679 ‘ContextValueAssociation’. It is a more user-friendly and code-management-orientated  
680 method and eases implementation through the use of a freely available tool for the creation  
681 of the Schematron/XSLT files.

682 In this method, the base code lists remain untouched. The extended, restricted, user-defined  
683 codes (permanent or temporary) are specified in separate genericode files, each with their  
684 own identifying list-level metadata.

685 The Context/Value Association (CVA) file specifies the XPath contexts of an XML  
686 document instance and the genericode file(s) applicable to each context. Unlike XSD  
687 enumerations binding the same enumeration to all contexts of a globally-declared and re-  
688 used business artefact (BBIE) in a message standard, the use of XPath in CVA provides for  
689 specifying different code lists at different contexts of one BBIE. Perhaps the user needs to  
690 validate against different lists of currency codes at different ‘currency code locations’ of a  
691 single XML document.

692 In other words, validation can be done on different context levels:

693

Context levels	Context address as specified in CVA file (examples)
System-wide	<code>address="ram:SpecifiedTradeProduct/ram:TypeCode"/&gt;</code>
Document-wide	<code>address="rsm:CrossIndustryInvoice//ram:InvoiceCurrencyCode"/&gt;</code>
Element specific	<code>address="rsm:CrossIndustryInvoice /rsm:SupplyChainTradeTransaction /ram:IncludedSupplyChainTradeLineItem /ram:SpecifiedTradeProduct /ram:ColourCode"/&gt;</code>

694

**Figure 10: Context levels and context address**

695 The Schematron expressions<sup>15</sup> leverage any code list metadata found in the BBIE’s  
696 supplementary components to ensure the appropriate genericode expression of codes is used  
697 in the given XML document instance. Finally, these XML expressions can be processed by  
698 applications creating visual interfaces in order to tailor drop-down lists of coded value  
699 domains presented to users.

700 A genericode file contains the following data which can be used during validation:

- 701 - code list values
- 702 - code list metadata

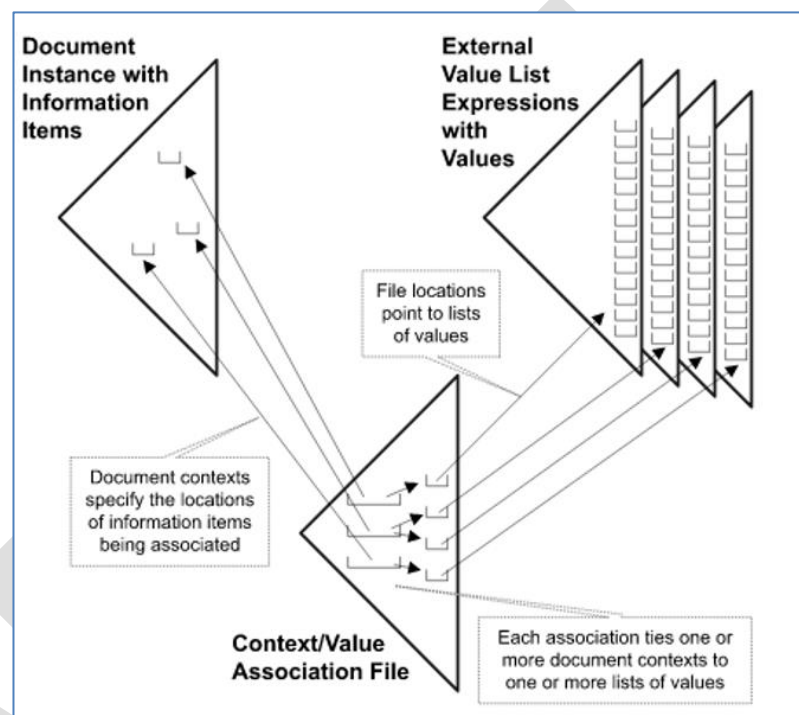

703

<sup>15</sup> Schematron rules are generated automatically by a free of charge tool, but users could write the rules themselves.

704 The code value found in the XML document instance will be checked against the genericode  
 705 files linked by association. The location of a genericode file is declared with URI address  
 706 and the identity of each code list is unique. An association links the document's context with  
 707 a set of genericode files.

708 Any supplementary component (metadata) present in the XML document instance is also  
 709 checked against the code list value metadata specified in the genericode file. All community  
 710 members use the same message schemas for the initial structural constraints, while the many  
 711 and varied and contextual requirements for value validation agreed upon between trading  
 712 partners, perhaps even in real time, are realized as needed.

713

714

716

717

### The Context/Value Association

718

719

720

721

722

The Context/Value Association file format is an XML vocabulary using address expressions to specify hierarchical document contexts and their associated constraints. A document context specifies one or more locations found in an XML document or other similarly structured hierarchy of information. A constraint is expressed as either an explicit expression evaluation or as a value inclusion in one or more controlled vocabularies of values.

723

724

This file format specification assumes a controlled vocabulary of values is expressed in an external resource described by the OASIS genericode standard.

725

726

For each code list scenario, the applicable CVA 'Value lists' (code lists) and 'Contexts' (associations) will be described in the following paragraphs.

727

728

### The concept of a masquerade

729

730

The CVA file employs the concept of a masquerade. The masquerade overlays the complete list's metadata in place of the customized code list's metadata during the validation process

731 in real time. This prevents confusion and ambiguity regarding the identity of the customized  
732 code list which is not and should not be identified as a complete list in its metadata.

733 A data element citing the full list will successfully validate against the extended or restricted  
734 list using the masquerade of the full list. This ensures multiple extended or restricted lists of  
735 the same full list can be uniquely identified and managed by their respective distinguished  
736 metadata.

737 The concept of masquerade is also used in case of combining code lists, in which of them is  
738 taken as the masquerade overlay. Different trading partners can mutually use different sets  
739 of code lists.

740

<b>Masquerade</b>
In this example, the masquerade overlays the “ISO3AlphaCurrencyCode” list’s metadata in place of the “InvoiceCurrencyTypeCodes” code list’s metadata.
<b>Example: Value lists</b>
<pre>&lt;ValueLists&gt;   &lt;ValueList xml:id="InvoiceCurrencyCodesD17B"     masqueradeUri= "../gc/ISO_ISO3AlphaCurrencyCode_2012-08-31.gc"/&gt;   &lt;ValueList uri= "../gc/InvoiceCurrencyTypeCodes.gc"/&gt; &lt;/ValueLists&gt;</pre>

742

Figure 12: Concept of masquerade

### 743 7.3.2.1 Restricted code lists

744 A restricted code list is a shorter version of the applicable full-list genericcode file. The  
745 masquerade ensures re-use of the metadata specified in the UNECE full code list.

746

<b>Restricting code values</b>	
In this example, the invoice currency code list (restricting of ISO code list) is used only for the TaxCurrencyCode element specified with the Header Trade Settlement component.	
<i>Example: Contexts</i>	<i>Example: Value lists</i>
<pre>&lt;Contexts&gt;   &lt;Context values=" InvoiceTaxCurrencyCodesD17B"     metadata="cctsV2.01-code"     address=" rsm:CrossIndustryInvoice/ rsm:SupplyChainTradeTransaction/ram :ApplicableHeaderTradeSettlement/ram:TaxCurrencyCode"/&gt; &lt;/Contexts&gt;</pre>	<pre>&lt;ValueLists&gt; &lt;ValueList xml:id="InvoiceTaxCurrencyCodesD17B" masqueradeUri= "../gc/ ISO_ISO3AlphaCurrencyCode_2012-08- 31.gc"/&gt; uri= "../gc/InvoiceTaxCurrencyTypeCodes.gc"/&gt; &lt;/ValueLists&gt;</pre>

747

Figure 13: Restricted code list

### 748 7.3.2.2 Extended code lists

749 The extended code list is a genericcode containing only the extended code values compared  
750 to the version of the applicable full-list genericcode file. The masquerade ensures re-use of  
751 the metadata specified in the full-list genericcode file.

752 The CVA file would express the union of the full-list genericcode file and the extended  
753 genericcode file. The masquerade would make the entire list appear to have the full-list  
754 genericcode file list’s metadata. In this way at no time is there an ambiguous publication of a  
755 mixed list with metadata that could be confused with the metadata of the published list.  
756 When the published list is revised, the extended code values are incorporated as in extended  
757 genericcode file.

758

Extending code values	
In this example, the ISO 3 alpha currency code list (base list) has been extended by the new ISO 3 alpha currency code list (containing only new currency code values). The code list is used only for the TaxCurrencyCode element specified with the Header Trade Settlement component.	
<i>Example: Contexts</i>	<i>Example: Value lists</i>
<pre> &lt;/Contexts&gt; &lt;Context values=" ISO_ISO3AlphaCurrencyCode_2012-08-31 NEW_ISO3AlphaCurrencyCode_2017-09-08"   metadata="cctsV2.01-code"   address=" rsm:CrossIndustryInvoice"/&gt; &lt;/Contexts&gt; </pre>	<pre> &lt;ValueLists&gt; &lt;ValueList xml:id=" ISO_ISO3AlphaCurrencyCode_2012-08-31"   uri=" ../gc/ ISO_ISO3AlphaCurrencyCode_2012-08- 31.gc"/&gt; &lt;ValueList xml:id="NEW_ISO3AlphaCurrencyCode"   masqueradeUri= " ../gc/ISO_ISO3AlphaCurrencyCode_2012- 08-31.gc "/&gt;   uri=" ../gc/ NEW_ISO3AlphaCurrencyCode.gc "/&gt; &lt;/ValueLists&gt; </pre>

Figure 14: Extended code list

759

### 760 7.3.2.3 Choosing or combining code lists

761 Combining code values of different code lists is the essence of genericcode/CVA. Users can  
762 create as many code lists as needed. A union of code lists means specifying multiple ‘Value  
763 lists’ and specifying these within the ‘Context value’ in the CVA file.

764

Combining code values	
In this example, the transport means type code list is combined with the transport means type code list of recommendation 28.	
<i>Example: Contexts</i>	<i>Example: Value lists</i>
<pre> &lt;Contexts&gt; &lt;Context values=" UNECE_TransportMeansTypeCode_2007 UNECE_Rec28_Codes_for_Types_of_ Means_of_Transport_2007"   metadata="cctsV2.01-code"   address=" rsm:CrossIndustryInvoice/rsm: SupplyChainTradeTransaction/ ram:ApplicableHeaderTradeDelivery/ ram:RelatedSupplyChainConsignment/ ram:SpecifiedLogisticsTransportMovement/ ram:UsedLogisticsTransportMeans/ram:TypeCod e "/&gt; &lt;/Contexts&gt; </pre>	<pre> &lt;/ValueLists&gt; &lt;ValueList xml:id="UNECE_TransportMeansTypeCode_2007"   uri=" ../gc/UNECE_TransportMeansTypeCode_2007. gc"/&gt; &lt;ValueList xml:id="UNECE_Rec28_Codes_for_Types_of_ Means_of_Transport_2007"   masqueradeUri= " ../gc/UNECE_TransportMeansTypeCode_2007.gc"/ &gt; &lt;/ValueLists&gt; </pre>

Figure 15: Comnined code list

765

### 766 7.3.2.4 User-defined code lists (permanent or temporary)

767 A user-defined code list is a genericcode file containing only the user-defined code values.  
768 This genericcode file would have its own identity. The user-defined permanent and/or  
769 temporary code values may be adopted in a new version of a standardized code list.

770

User-defined code values
In this example, the user-defined end item type code list is only applicable for the element EnditemTypeCode used within the below specified XPATH.

<i>Example: Contexts</i>	<i>Example: Value lists</i>
<pre data-bbox="280 277 823 573">&lt;Contexts&gt;   &lt;Context values=" User_Defined_Enditem_TypeCode_2017" metadata="cctsV2.01-code" address=" rsm:CrossIndustryInvoice/rsm:SupplyChainTrade Transaction/ram:IncludedSupplyChainTradeLineI tem/ram:SpecifiedTradeProduct/ram:EndItemTyp eCode"/&gt; &lt;/Contexts&gt;</pre>	<pre data-bbox="849 277 1406 456">&lt;/ValueLists&gt;   &lt;ValueList xml:id="User_Defined_Enditem_TypeCode_2017" uri=" ../gc/ User_Defined_Enditem_TypeCode_2017.gc"/&gt; &lt;/ValueLists&gt;</pre>

Figure 16: User-defined code list

771

### 772 7.3.2.5 Code lists published by other organizations

773 An external maintained code list could be treated as a user defined code list (see previous  
774 paragraph).

### 775 7.3.2.6 Impacts for a real-life environment

776 From a user-perspective, the Schematron/XSLT using genericode/CVA method offers users  
777 the following advantages:

- 778 • A user-friendly code management solution solving all issues identified by the code  
779 management project team.
- 780 • Easy implementation through the use of a freely available tool for the creation of the  
781 Schematron/XSLT files.
- 782 • Users can focus on the maintenance of genericode files and context associations,  
783 without having to write extensive files expressing their needs.
- 784 • Code list values and metadata are stored in a standardized file format (genericode).
- 785 • Associations between document context and applicable code lists are stored in a  
786 standardized file format (CVA).
- 787 • By using the ‘masquerade’ function, unions of code lists are recognized as one single  
788 code list during validation and can be presented in user dropdown lists.
- 789 • Through the existence of genericode files and the ‘masquerade’ function, the  
790 supplementary components can be checked to avoid any ambiguity.

791

## 792 9 Publication format code lists

### 793 9.1 Genericode

794 Genericode is a standard format for defining code lists.

795 The genericode standard offers:

- 796 - a XML format designed to support interchange or distribution of machine-readable  
797 code list information between systems.
- 798 - a XML format that can be transformed into formats suitable for run-time usage, or  
799 loaded into systems that perform run-time processing using code list information.
- 800 - a tabular structure for code list information:
  - 801 - each row in the table represents a single distinct entry in the code list, i.e. each  
802 row represents a single uniquely identifiable item in the code list.
  - 803 - each column in the table represents a metadata value that can be defined for  
804 each distinct entry in the code list. Each column is either required or optional.

805 Genericode is used, among other things, by UBL (Universal Business Language) and FpML  
806 (Financial Products Markup Language). Genericode is advised by the Dutch government,  
807 the education world (New Zealand) and electronic commerce (e-Commerce, EDI) as  
808 complementary to UBL. The standard is used worldwide.

809 Besides, genericode files are an essential component within the code value validation  
810 method ‘Schematron/XSLT using Genericode/CVA’. In fact, they could be used as a  
811 component within every code validation environment. In addition, the genericode standard  
812 format for defining code lists is translation syntax independent. From a genericode file, XSD  
813 code list schema modules or any other format could be created. This will ease the  
814 maintenance of code lists in environments, such as where UN/EDIFACT and UN/CEFACT  
815 XML use the same code list repository.

816 The two-phase validation methods, described in this document and beyond, will benefit from  
817 a publication of code lists in one single representation format. Both UN/EDIFACT and  
818 UN/CEFACT XML messages may use one or more code lists during a two-phase validation  
819 process.

### 820 9.2 Code list Document

821 The OASIS Code List Representation format<sup>16</sup>, “genericode”, is a single model and XML  
822 format (with a W3C XML Schema) that can encode a broad range of code list information.  
823 The XML format is designed to support interchange or distribution of machine-readable  
824 code list information between systems. Note that genericode is not designed as a run-time  
825 format for accessing code list information, and is not optimized for such usage. Rather, it is  
826 designed as an interchange format that can be transformed into formats suitable for run-time  
827 usage, or loaded into systems that perform run-time processing using code list information.

Figure 18: Example Genericcode file

883 **10 Definition of Terms**

Term	Definition
Restriction	Removing code values from an existing code lists or by saving the changed one as a new code list.
Choice (of code lists)	XML Schema choice element allows only one of the elements contained in the <choice> declaration to be present within the containing element. In other words one of the code lists is applicable for the element involved.
Coupled	During the validation of the document instance, code values are validated simultaneously with the message structure constraints (one-phase validation process).
EDIFACT	The EDIFACT standard provides a set of syntax rules to structure data for interactive exchange of standard messages between multi-country and multi-industry.
Extension	Adding new code values to an existing code list or by saving the changed one as a new code list.
ISO	International Standards Organization
One-phase validation process	Both message structure and code values constraints are validated simultaneously.
Schematron	Schematron is a rule-based validation language for making assertions about the presence or absence of patterns in XML trees.
Sub-set	See restriction
Superset	See extension
Two-phase validation process	Only message structure constraints are validated during this process phase.
Union (of code lists)	The union element defines a simple type as a collection (union) of values from specified simple data types. In other words it combines one or more code lists.
Uncoupled	During the validation of the document instance, code values are not validated simultaneously with the message structure constraints, but validated in a next phase (two-phase validation process).
Validating	Checking that a document instance meets specifications and fulfills its intended purpose.
XML	Extensible Markup Language (XML) is a markup language that defines a set of rules for encoding documents in a format that is both human-readable and machine-readable through use of tags that can be created and defined.
XSD	XSD (XML Schema Definition), a recommendation of the World Wide Web Consortium (W3C), specifies how to formally describe the elements in an Extensible Markup Language (XML) document.

884
